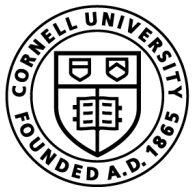
Lecture 5:
Defining Functions
(Ch. 3.4-3.11)

CS 1110

Introduction to Computing Using Python



Cornell Bowers CIS
Computer Science

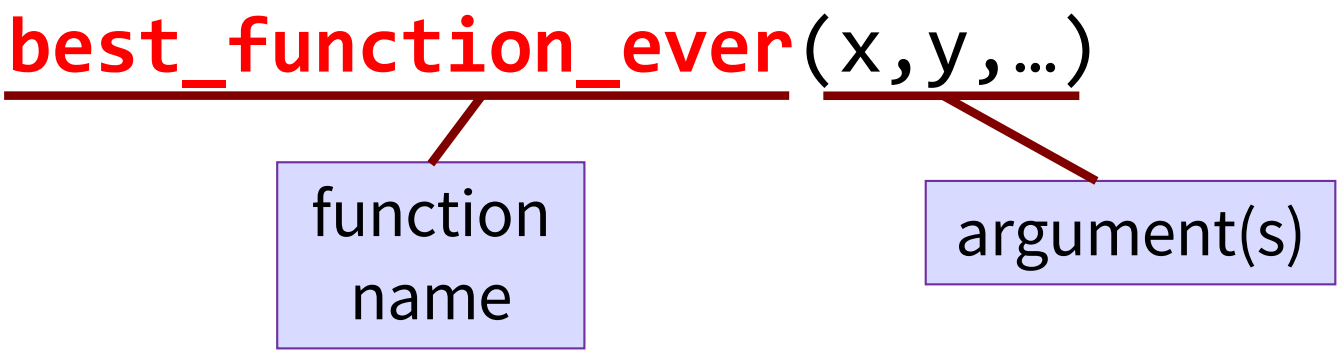
[E. Andersen, A. Bracy, D. Gries, L. Lee, S. Marschner, C. Van Loan, W. White]

Announcements

- A1 goes out tomorrow
  - Partners will also be announced tomorrow
- Academic Integrity Quiz due tomorrow
- 1-on-1's go live Friday

From Last Time: Function Calls

- Function calls have the form:

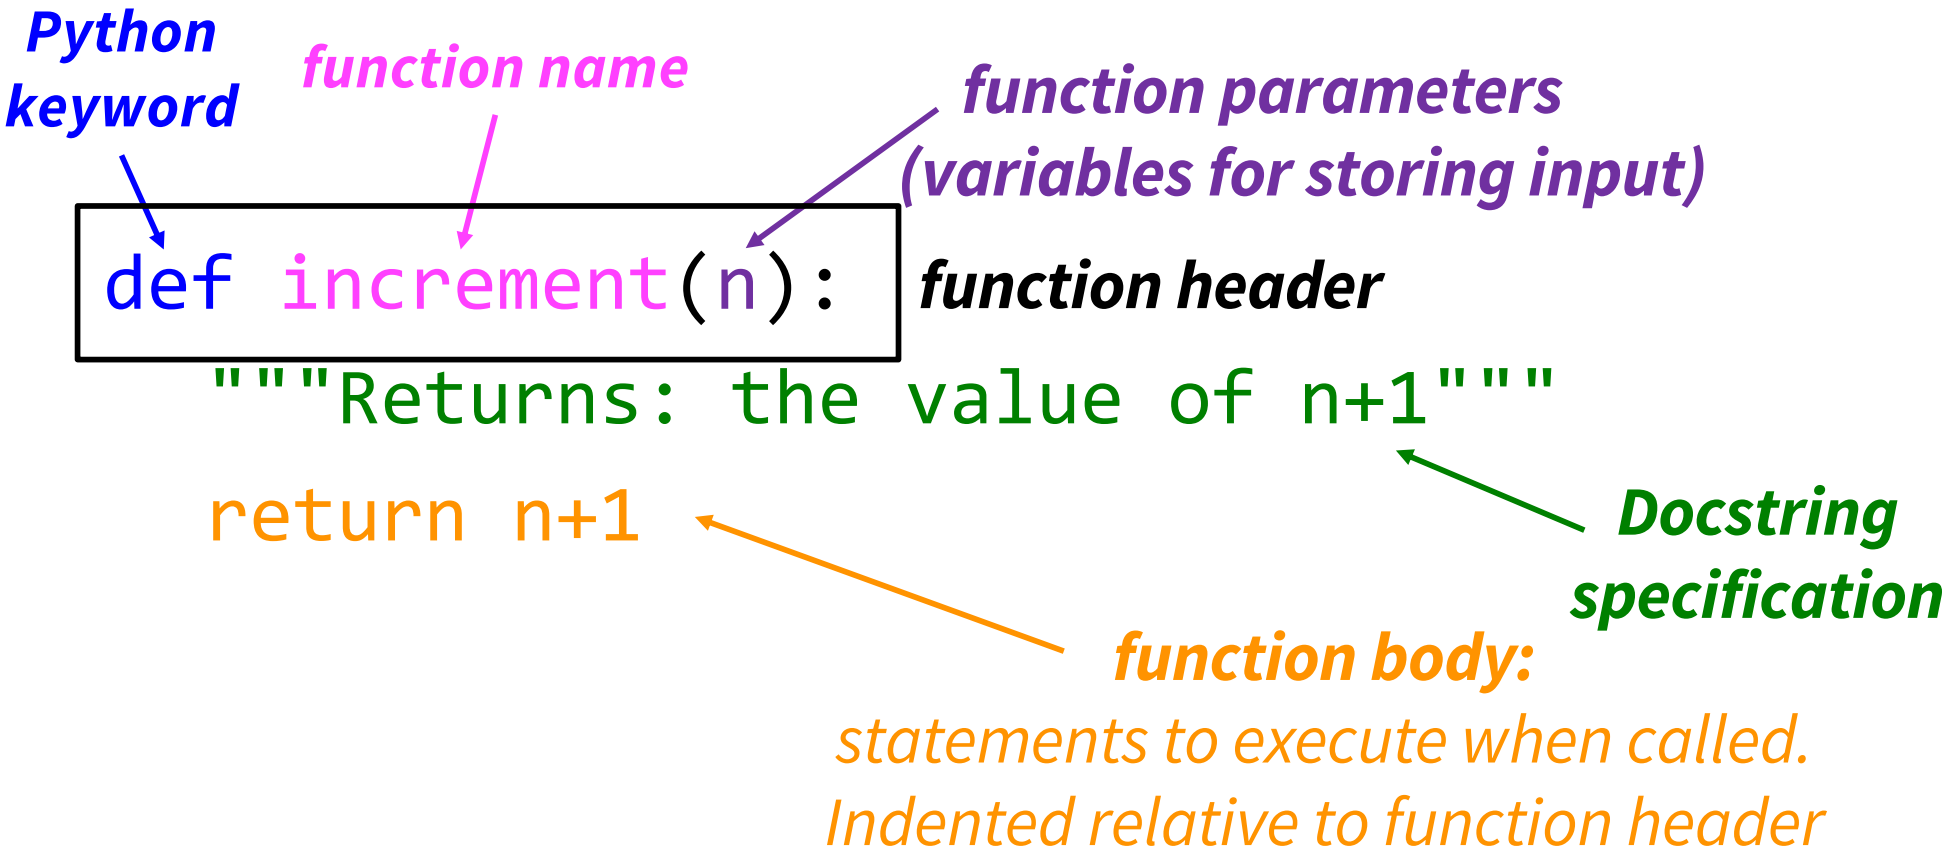


- Arguments: values given as inputs
  - Separated by commas
  - Can be any expression

A function might have 0, 1, … or many arguments

Let's define our own functions!

Anatomy of a Function Definition



The `return` Statement

- Passes a value from the function to the caller
- Format: `return` *<expression>*
- Any function body statements placed after a `return` statement will be ignored
- Optional
  - if absent, special value `None` will be sent back

Organization of a Module

```
# simple_math.py

def increment(n):
    return n+1

increment(2)
```

simple_math.py

- Function definition goes before any code that calls that function
- There can be multiple function definitions
- Can organize function definitions in any order

Function Definitions vs. Calls

```
# simple_math.py

def increment(n):
    return n+1

increment(2)
```

simple_math.py

Function definition

- Defines what function will do
- Declaration of parameters (n in this case)
- **Parameter:** variable where input to function is stored

Function call

- Command to do the function
- Argument to assign to function parameter (Argument **2** to be assigned to parameter **n** in this case)
- **Argument:** an input value to assign to the function parameter when it is called

Executing the script `simple_math.py`

```
C:/> python simple_math.py
```

```
# simple_math.py

"""script that defines
and calls one simple
math function"""

def increment(n):
    """Returns: n+1"""
    return n+1

x = increment(2)
```

simple_math.py

Python skips

Python skips

Python learns about the function (1)

*Python skips everything inside the function **until the function is called***

Python executes this statement (3)

To evaluate the RHS, python executes the function body (2)

return vs. print

```
# simple_math.py

"""script that defines
and calls one simple
math function"""

def increment(n):
    """Returns: n+1"""
    return n+1

x = increment(2)
```

simple_math.py

```
C:/> python simple_math.py
C:/>
```

Notice that this script does not print anything!

*The function **returns** the value (it gets saved in x) but does not print it.*

If you want the function to also print to the screen, it needs a print statement.

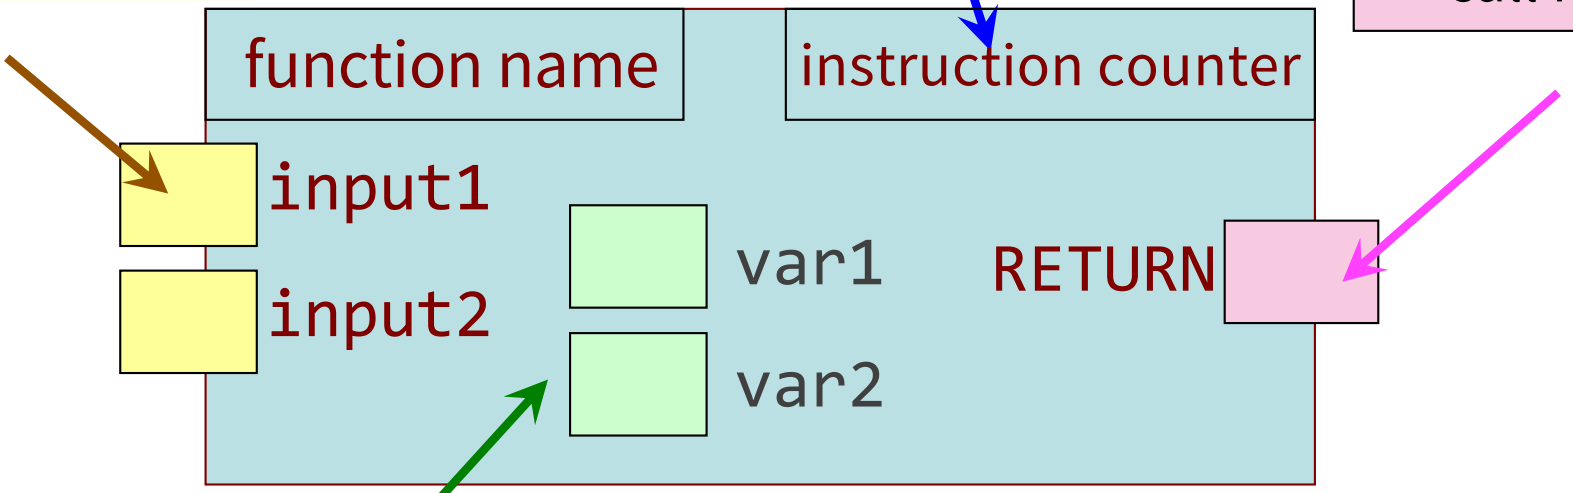
Drawing what functions "look like" in memory

Call Frame: representation of function call

Draw parameters as variables "entering" the call frame

- Line number of **next** statement in the function to execute
- Starts w/ 1st statement in function body

Draw RETURN value as a variable "leaving" the call frame



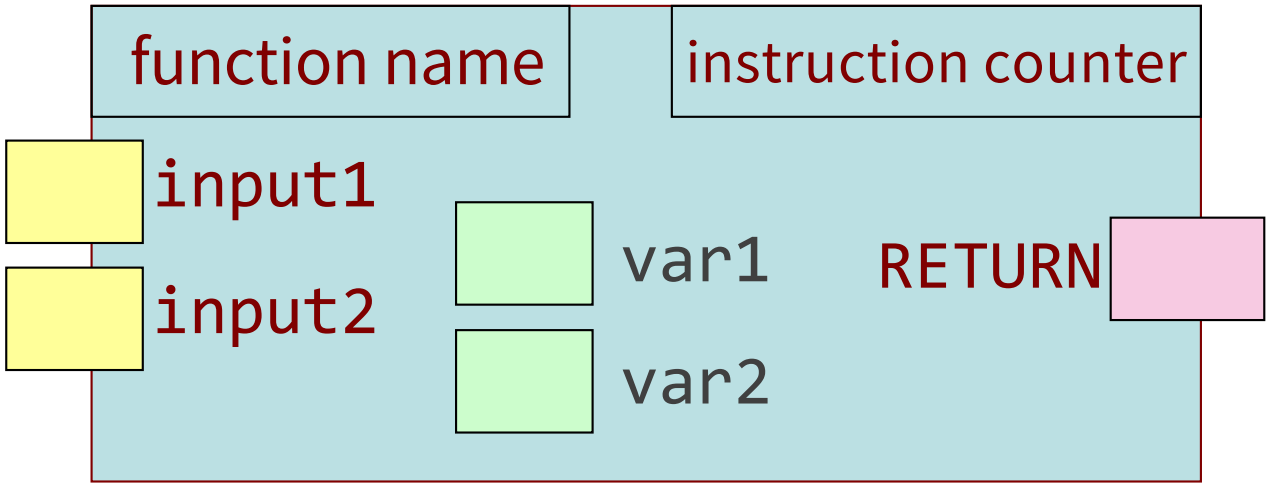
Draw local variables (introduced later) inside the call frame (they "exist" only as the function is being executed and not afterwards)

Drawing what functions "look like" in memory

Call Frame: representation of function call

Not just a pretty picture!

The information in this picture depicts *exactly* what is stored in memory on your computer.



Note: slightly different than in the book (3.9) Please do it this way.

Example: get_feet in height.py module

```
>>> import height
>>> height.get_feet(68)
```

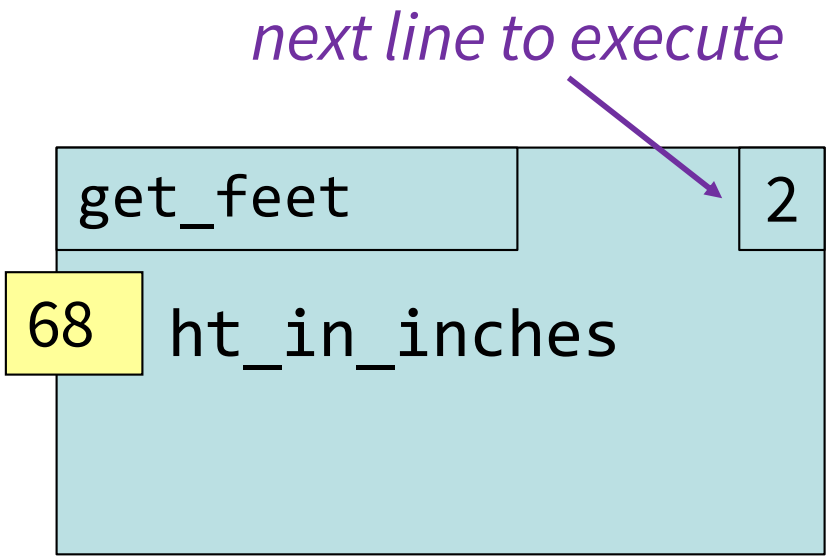
```
# height.py

def get_feet(ht_in_inches):
    return ht_in_inches // 12
```

height.py

Example: `get_feet(68)` (slide 1)

```
>>> import height
>>> height.get_feet(68)
```



PHASE 1: Set up call frame

1. Draw a frame for the call
2. Assign the argument value to the parameter (in frame)
3. Indicate next line to execute

```
# height.py

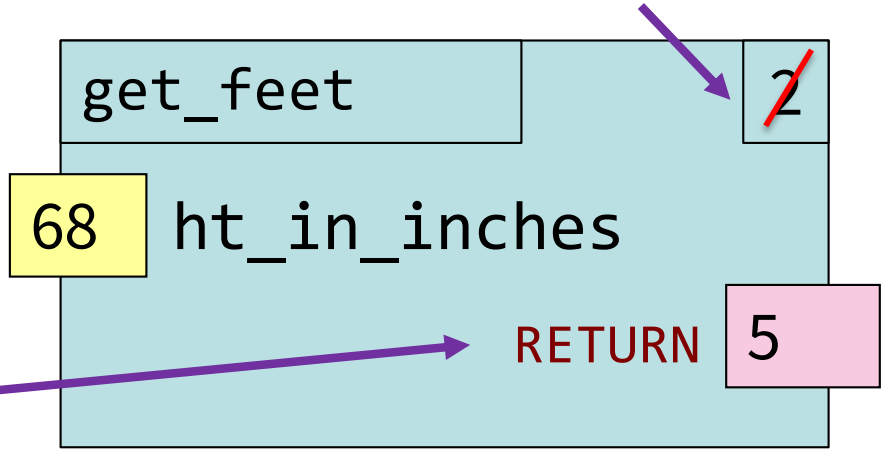
1 def get_feet(ht_in_inches):
2     return ht_in_inches // 12
```

height.py

Example: `get_feet(68)` (slide 2)

```
>>> import height
>>> height.get_feet(68)
```

The return terminates; no next line to execute



PHASE 2:

Execute function body

Return statement creates a special variable for result

```
# height.py

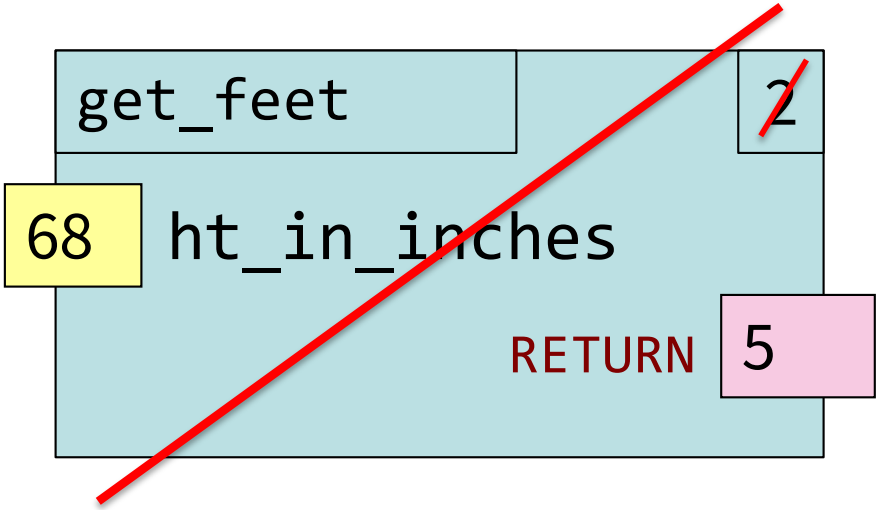
1 def get_feet(ht_in_inches):
2     return ht_in_inches // 12
```

height.py

Example: `get_feet(68)` (slide 3)

```
>>> import height
>>> height.get_feet(68)
5
>>>
```

Python interactive mode evaluates the expression and reports



PHASE 3: Delete (cross out) call frame

```
# height.py

1 def get_feet(ht_in_inches):
2     return ht_in_inches // 12
```

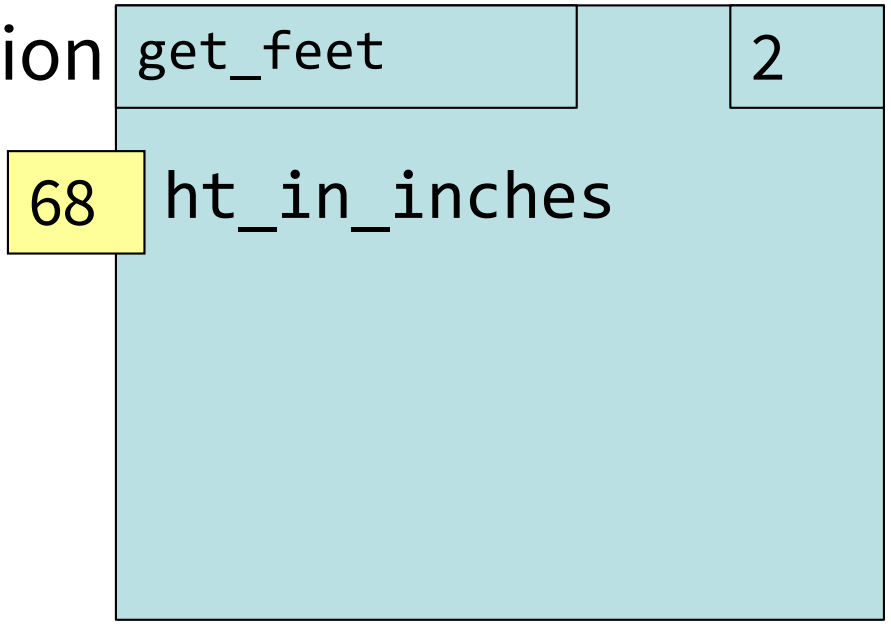
height.py

Local Variables (1)

Call frames can contain “local” variables

- A variable created in the function

```
>>> import height2
>>> height2.get_feet(68)
```



```
# height2.py

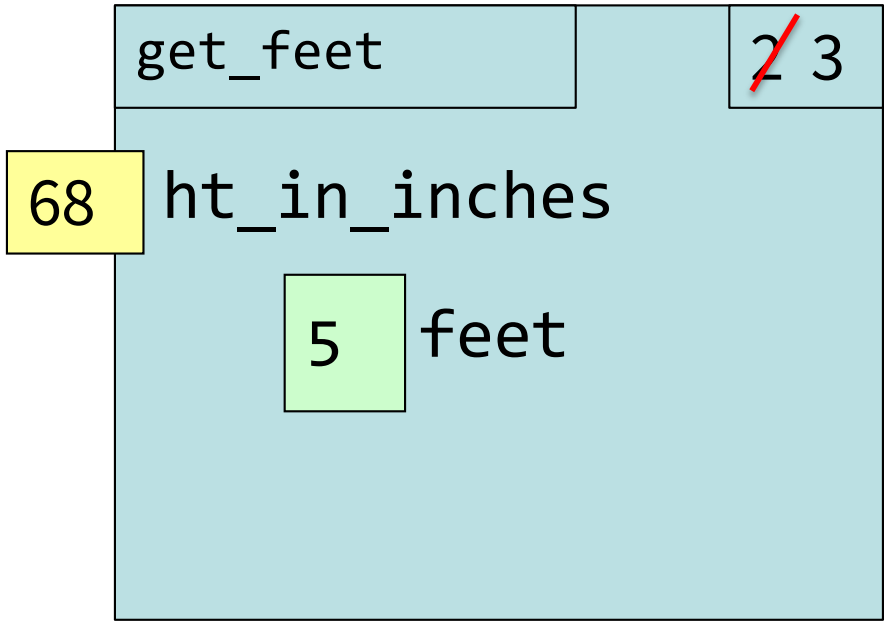
1 def get_feet(ht_in_inches):
2     feet = ht_in_inches // 12
3     return feet
```

height2.py

Local Variables (2)

Call frames can contain “local” variables

```
>>> import height2
>>> height2.get_feet(68)
```



```
# height2.py

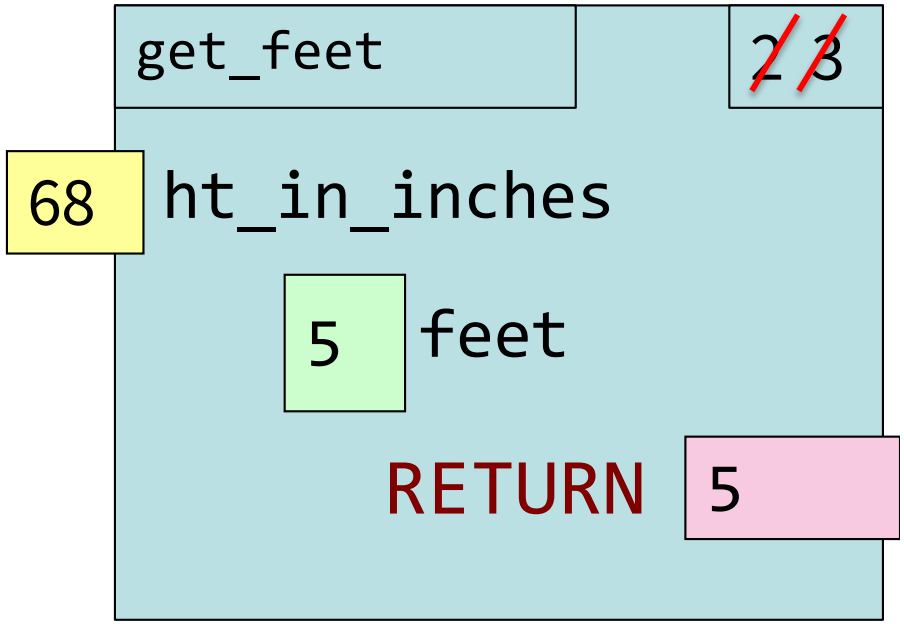
1 def get_feet(ht_in_inches):
2     feet = ht_in_inches // 12
3     return feet
```

height2.py

Local Variables (3)

Call frames can contain “local” variables

```
>>> import height2
>>> height2.get_feet(68)
```



```
1 def get_feet(ht_in_inches):
2     feet = ht_in_inches // 12
3     return feet
```

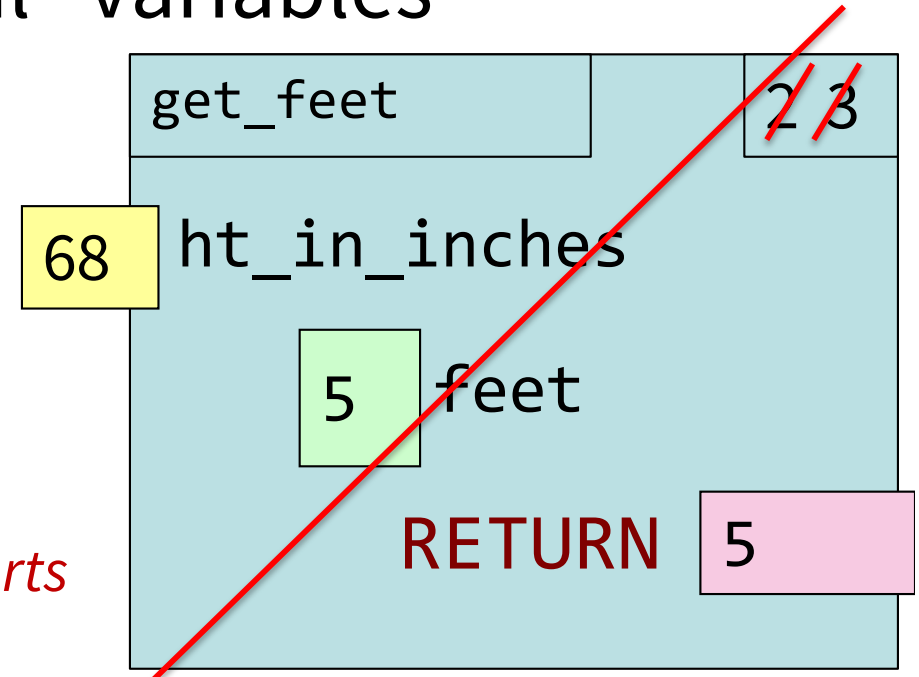
height2.py

Local Variables (4)

Call frames can contain "local" variables

```
>>> import height2
>>> height2.get_feet(68)
5
>>>
```

Python interactive mode evaluates the expression and reports



```
# height2.py

def get_feet(ht_in_inches):
    feet = ht_in_inches // 12
    return feet
```

height2.py

Variables are gone! This function is over.

Exercise #1

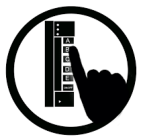
Function Definition

```
1 def foo(a,b):
2       x = a
3       y = b
4       return x*y+y
```

Function Call

```
>>> foo(3,4)
```

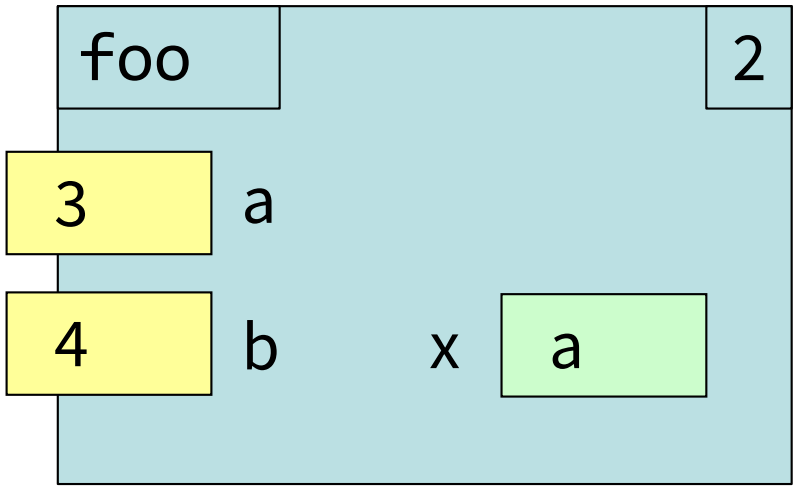
What does the frame look like at the start?



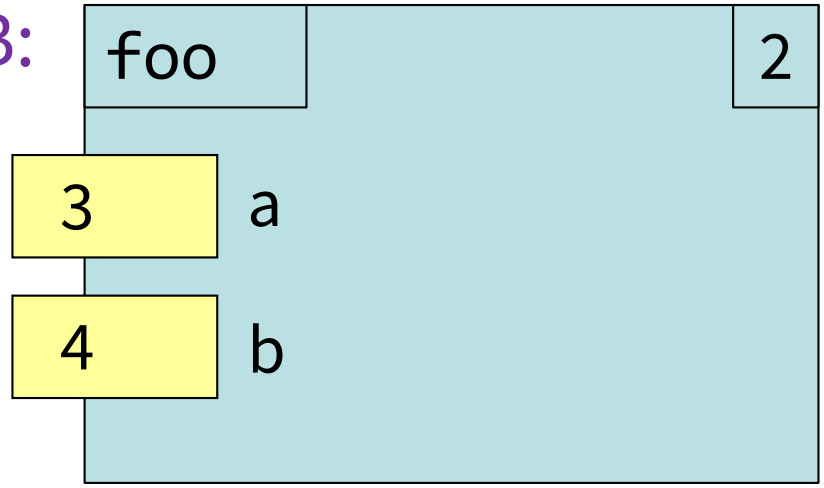
```
1 def foo(a,b):
2       x = a
3       y = b
4       return x*y+y
```

Which is Closest to Your Answer?

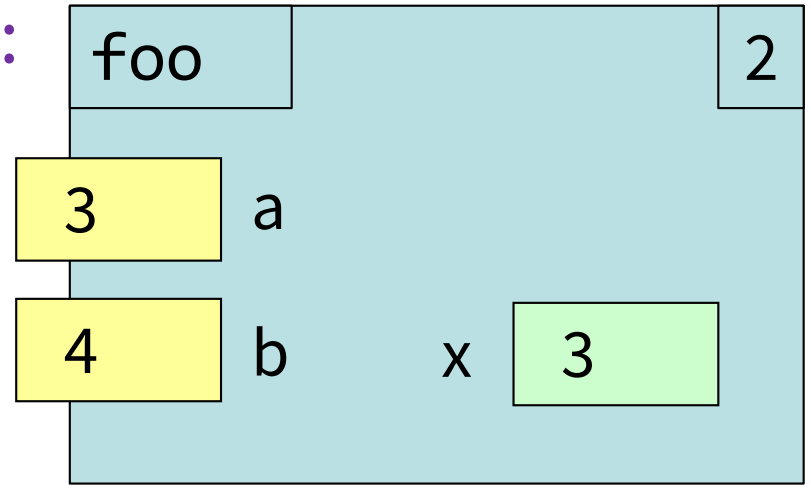
A:



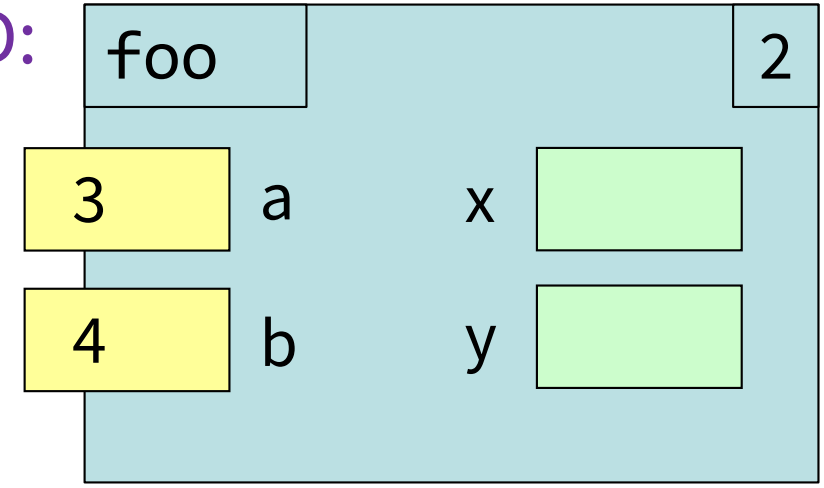
B:

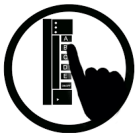


C:



D:





Exercise #2

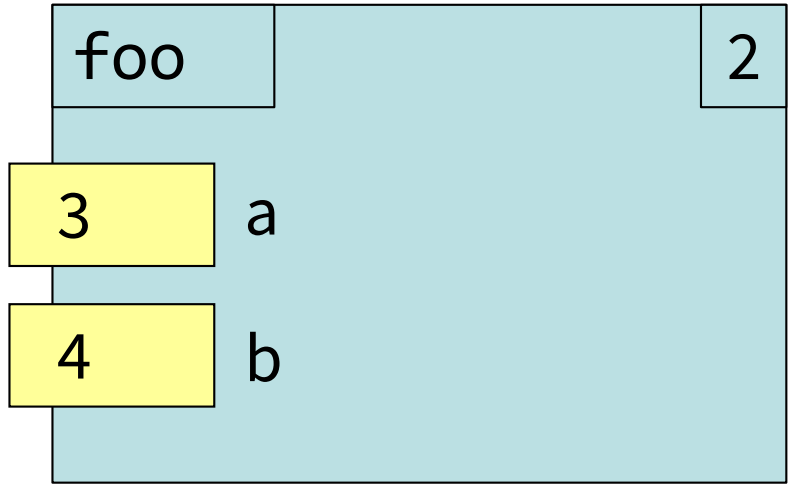
Function Definition

```
1 def foo(a,b):
2       x = a
3       y = b
4       return x*y+y
```

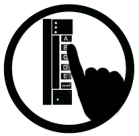
Function Call

```
>>> foo(3,4)
```

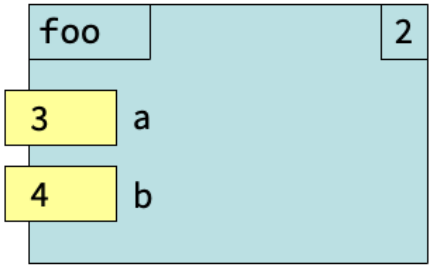
B:



What is the next step?

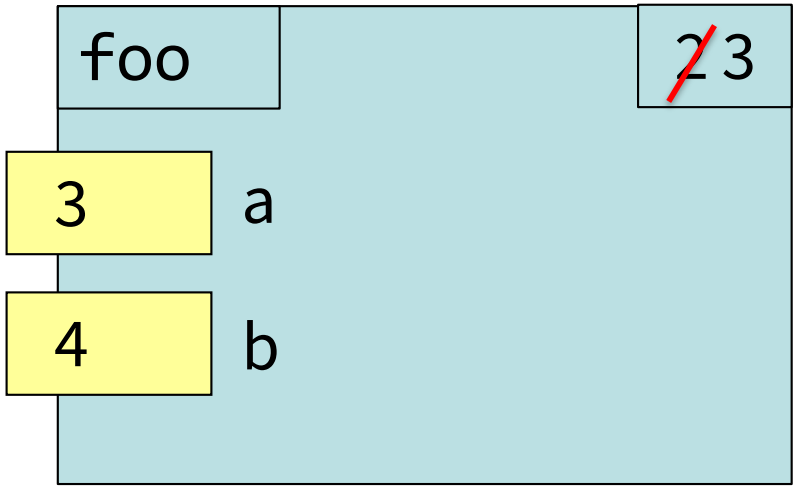


```
1 def foo(a,b):
2       x = a
3       y = b
4       return x*y+y
```

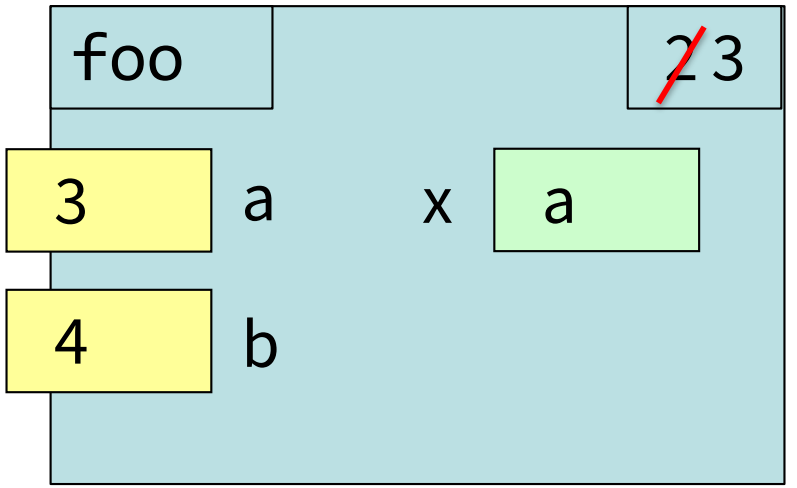


Which is Closest to Your Answer?

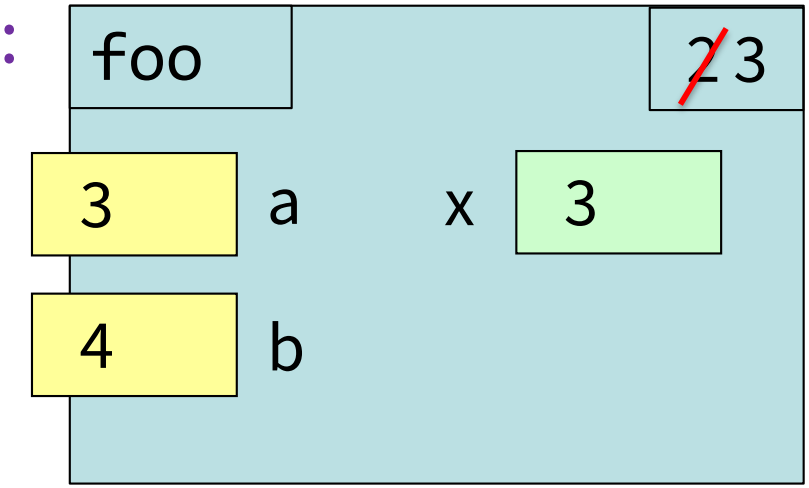
A:



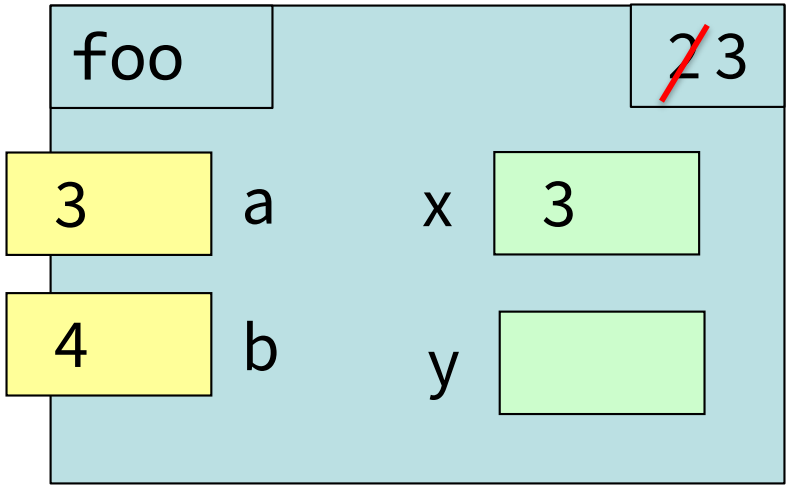
B:

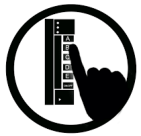


C:



D:





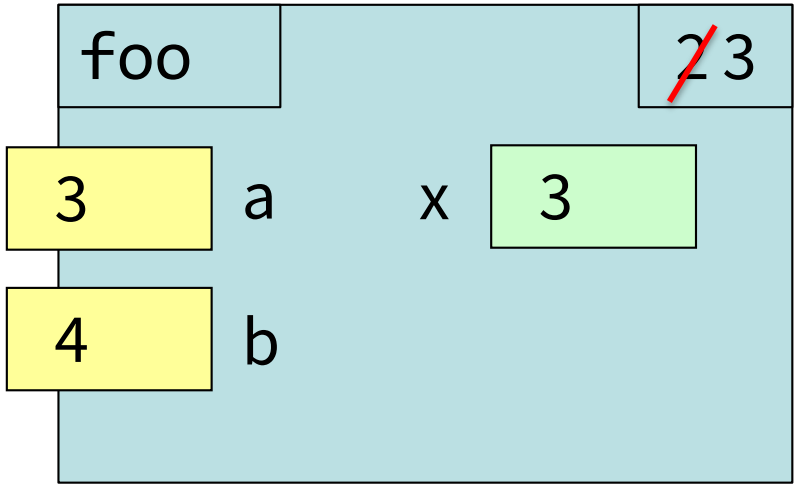
Exercise Time *(no poll, just discuss)*

Function Definition

```
1 def foo(a,b):
2       x = a
3       y = b
4       return x*y+y
```

Function Call

```
>>> foo(3,4)
```



What is the next step?

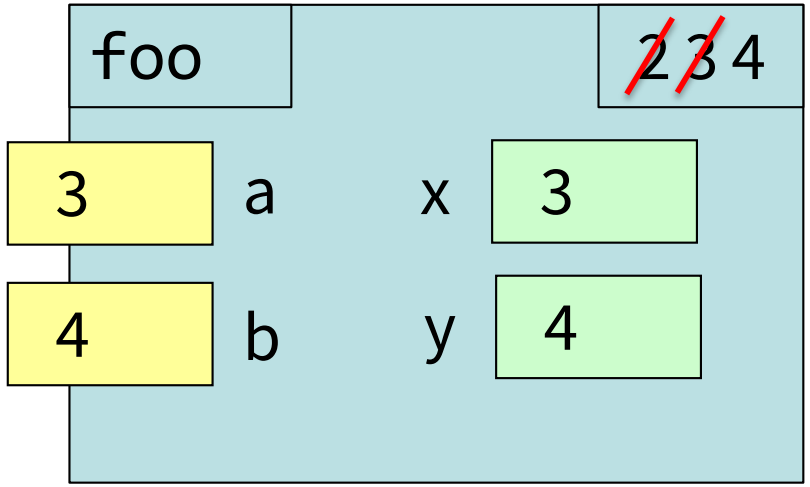
Exercise #3

Function Definition

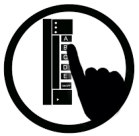
```
1 def foo(a,b):
2       x = a
3       y = b
4       return x*y+y
```

Function Call

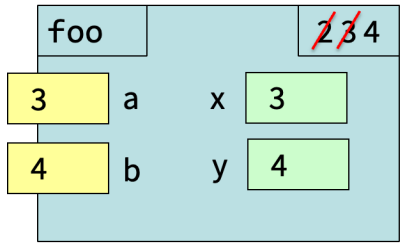
```
>>> foo(3,4)
```



What is the next step?

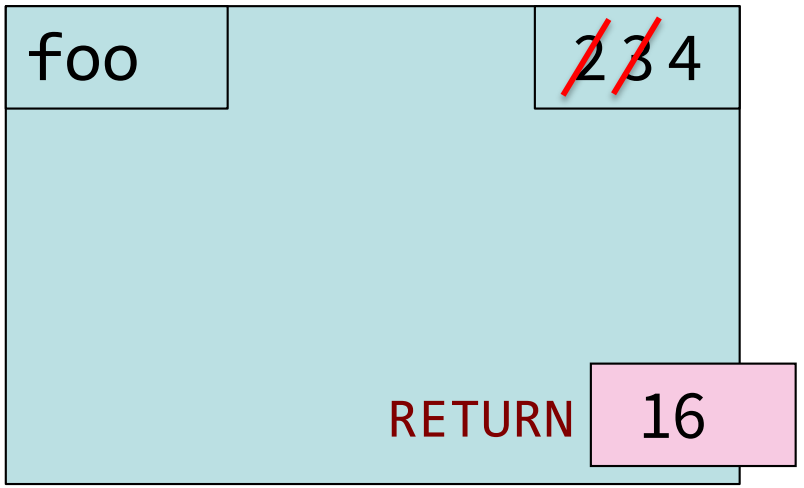


```
1 def foo(a,b):
2       x = a
3       y = b
4       return x*y+y
```

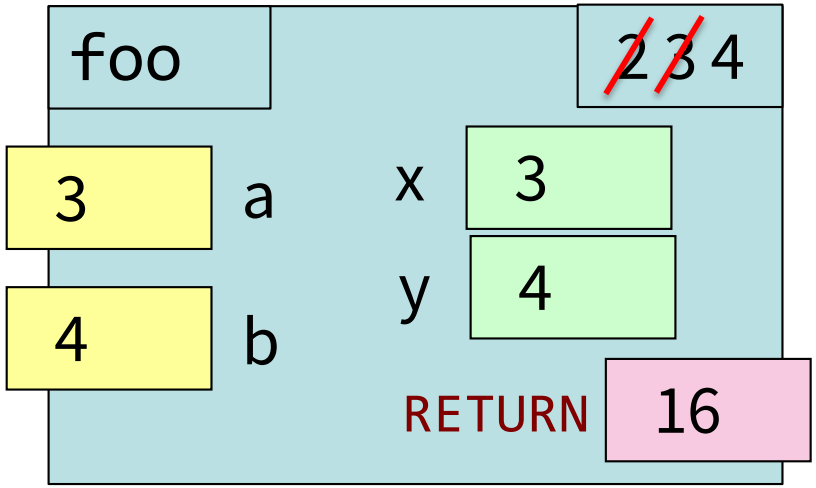


Which is Closest to Your Answer?

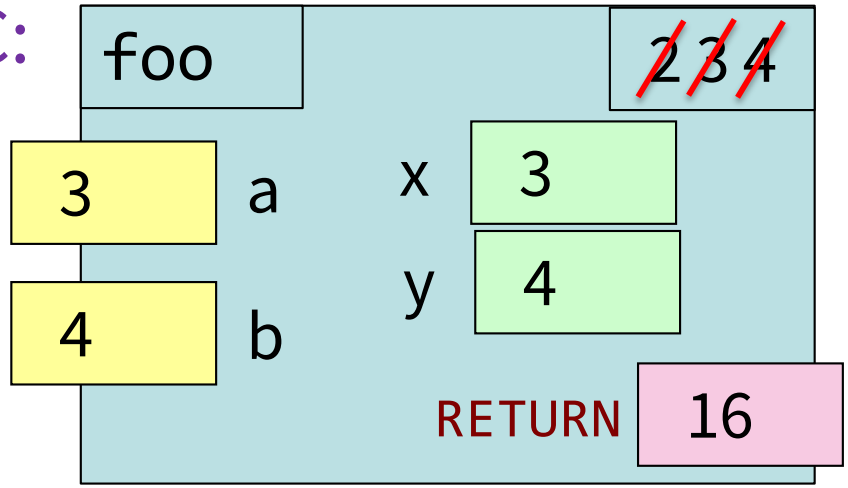
A:



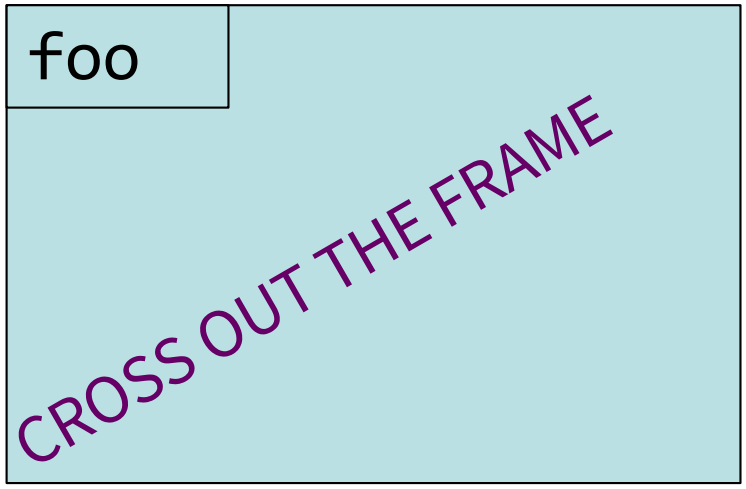
B:



C:



D:



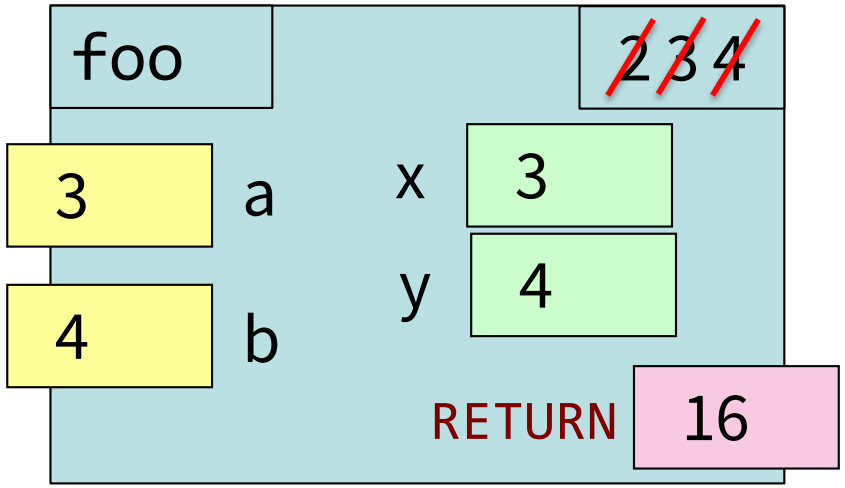
Exercise Time *(no poll, just discuss)*

Function Definition

```
1 def foo(a,b):
2       x = a
3       y = b
4       return x*y+y
```

Function Call

```
>>> foo(3,4)
```



What is the next step?

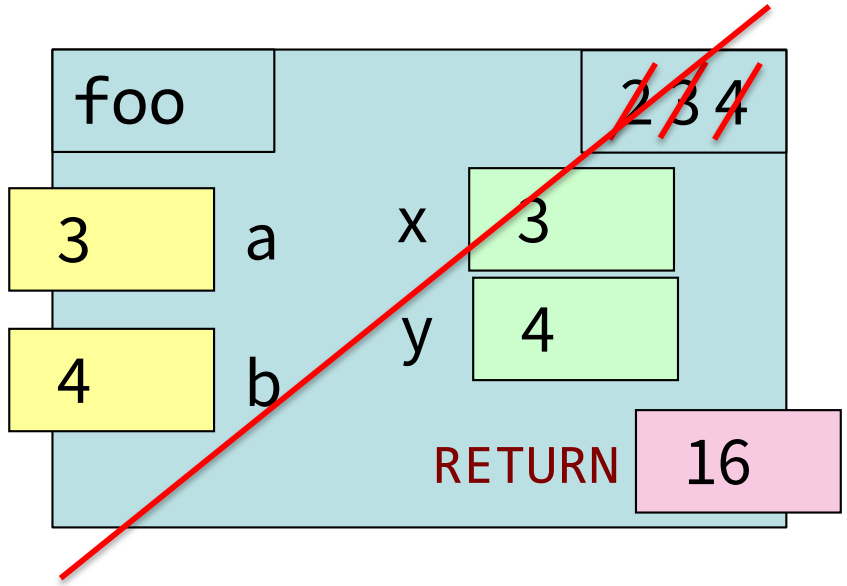
Exercise Time

Function Definition

```
1 def foo(a,b):
2       x = a
3       y = b
4       return x*y+y
```

Function Call

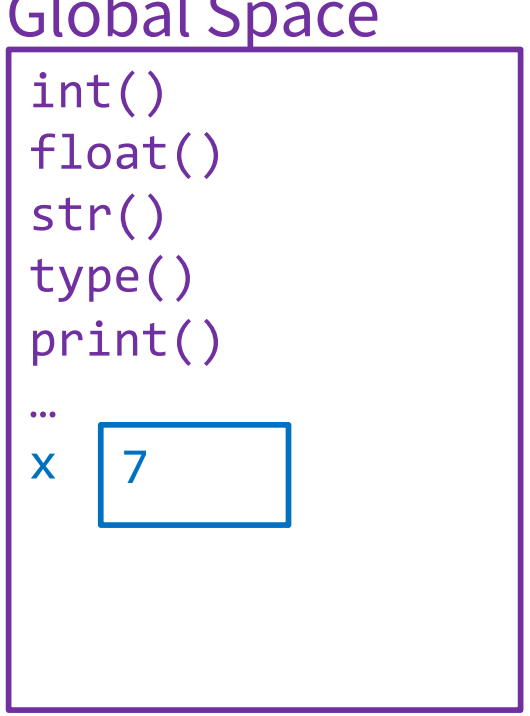
```
>>> foo(3,4)
16
>>>
```



Global Space

= the purple box we previously labeled
"What Python can access directly"

- Top-most location in memory
- Variables in Global Space called Global Variables
- Functions can access anything global space (see next slides)

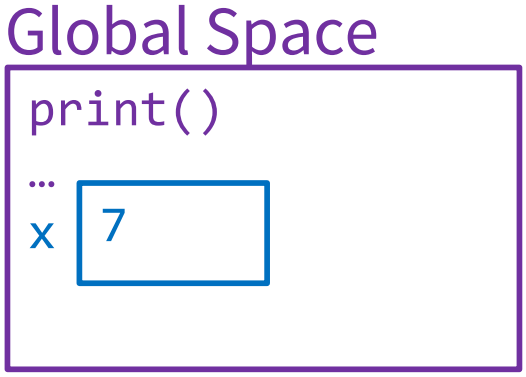


```
C:\> python
>>> x = 7
>>>
```

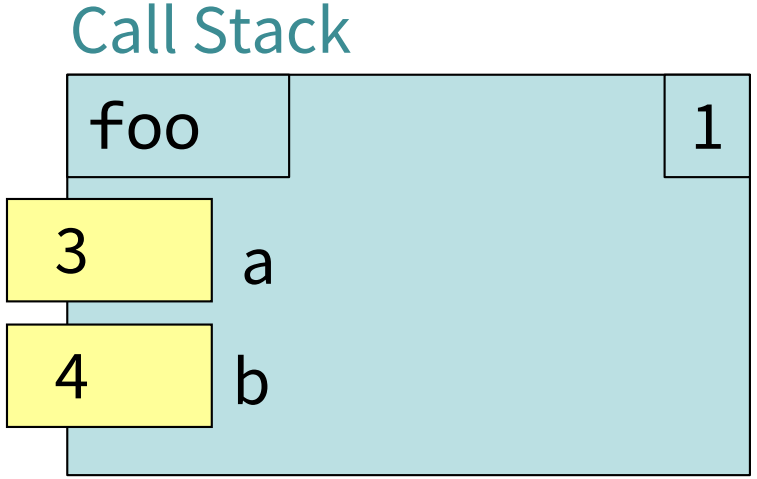
Call Stack

= the place in memory where the Call Frames live

Functions can only access the variables in their Call Frame or the Global Space.



This is the Call Frame for the function **foo**. *It is created in response to a function call and lives on the Call Stack, distinct from the Global Space.*



```
>>> foo(3,4)
```

Function Access to Global Space (1)

```
# height3.py

1 INCHES_PER_FT = 12
2 def get_feet(ht_in_inches):
3     feet = ht_in_inches // INCHES_PER_FT
4     return feet

5 answer = get_feet(68)
6 print(answer)
```

Global Space

```
print()
…
```

Python just started. It has all the built-in functions. It hasn't read any of the module yet.

```
C:\> python height3.py
```

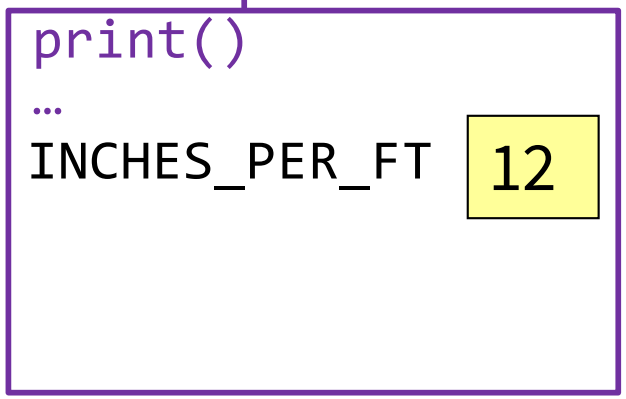
Function Access to Global Space (2)

```
# height3.py

1 INCHES_PER_FT = 12
2 def get_feet(ht_in_inches):
3     feet = ht_in_inches // INCHES_PER_FT
4     return feet

5 answer = get_feet(68)
6 print(answer)
```

Global Space



Python just read line 1 of the module.
A variable has been added to the Global Space.

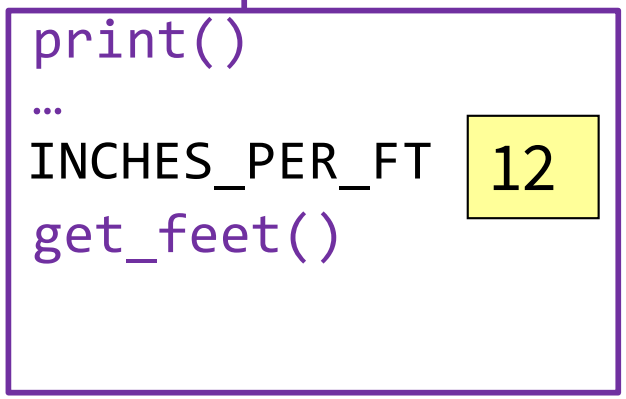
Function Access to Global Space (3)

```
# height3.py

1 INCHES_PER_FT = 12
2 def get_feet(ht_in_inches):
3     feet = ht_in_inches // INCHES_PER_FT
4     return feet

5 answer = get_feet(68)
6 print(answer)
```

Global Space



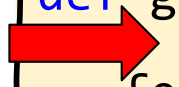
Python just read line 2 of the module.
A new function has been added to the Global Space.
Note: python has not yet looked inside the function.

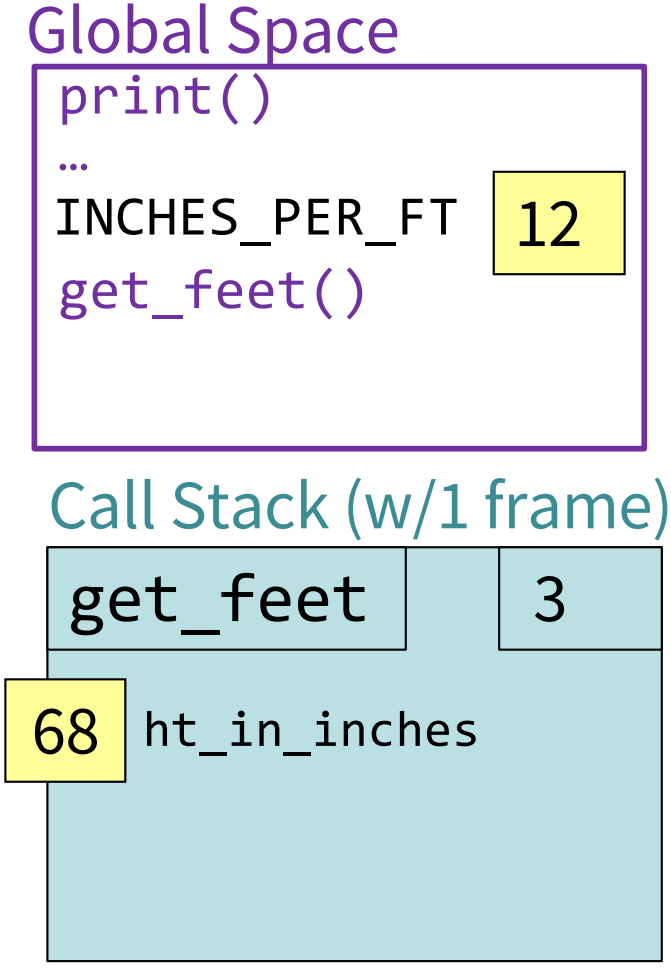
Function Access to Global Space (4)

```
# height3.py

1 INCHES_PER_FT = 12
2 def get_feet(ht_in_inches):
3     feet = ht_in_inches // INCHES_PER_FT
4     return feet

5 answer = get_feet(68)
6 print(answer)
```





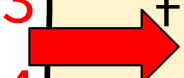
To execute the assignment statement on line 5, Python needs to evaluate the RHS. Python creates a call frame for the function, which lives on the Call Stack.

Function Access to Global Space (5)

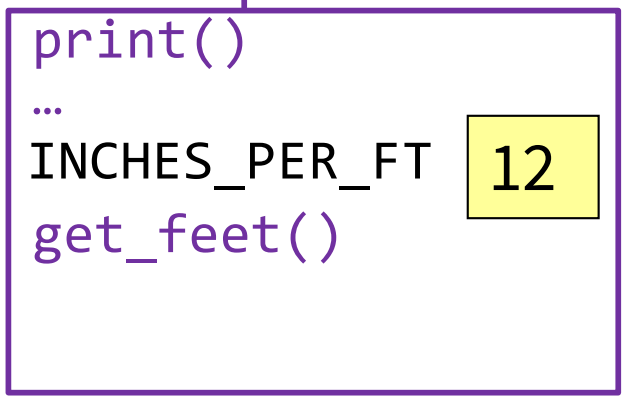
```
# height3.py

1 INCHES_PER_FT = 12
2 def get_feet(ht_in_inches):
3     feet = ht_in_inches // INCHES_PER_FT
4     return feet

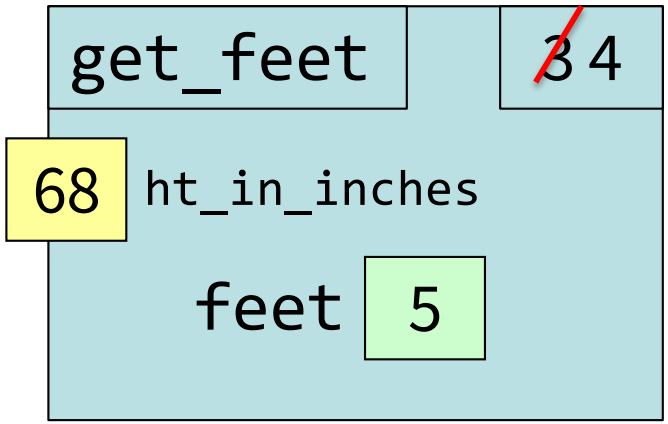
5 answer = get_feet(68)
6 print(answer)
```



Global Space



Call Stack



Python has just executed line 3.
A new local variable feet has been created inside get_feet's Call Frame.

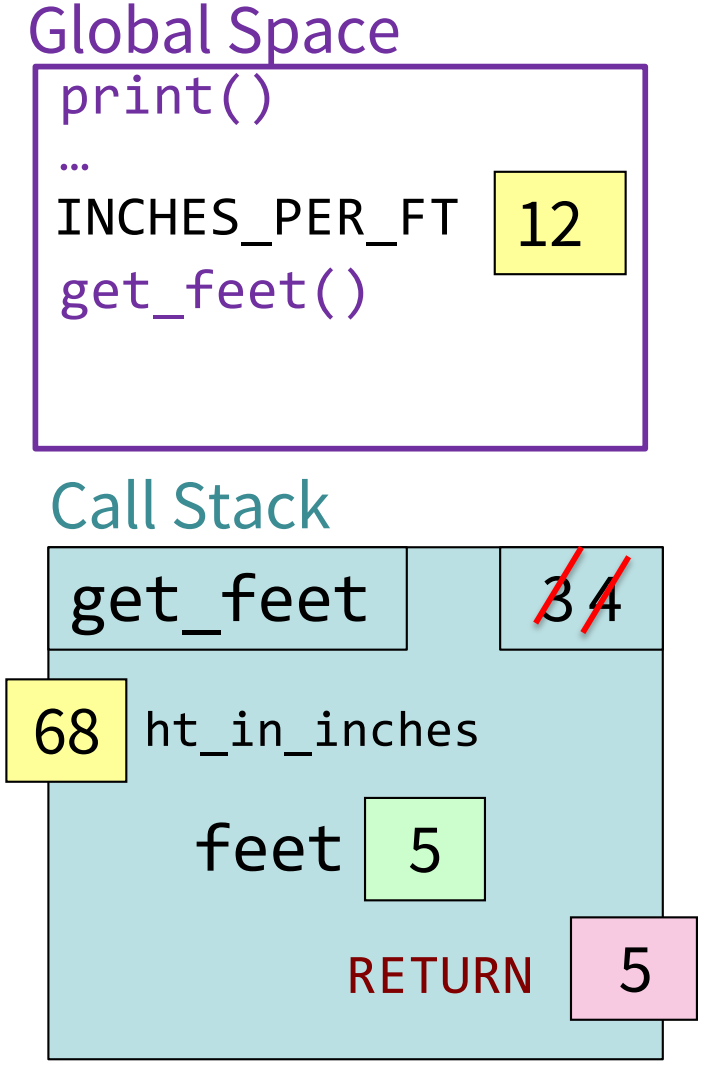
Function Access to Global Space (6)

```
# height3.py

1 INCHES_PER_FT = 12
2 def get_feet(ht_in_inches):
3     feet = ht_in_inches // INCHES_PER_FT
4     return feet

5 answer = get_feet(68)
6 print(answer)
```

Python has just executed line 4.
A return value has been created.

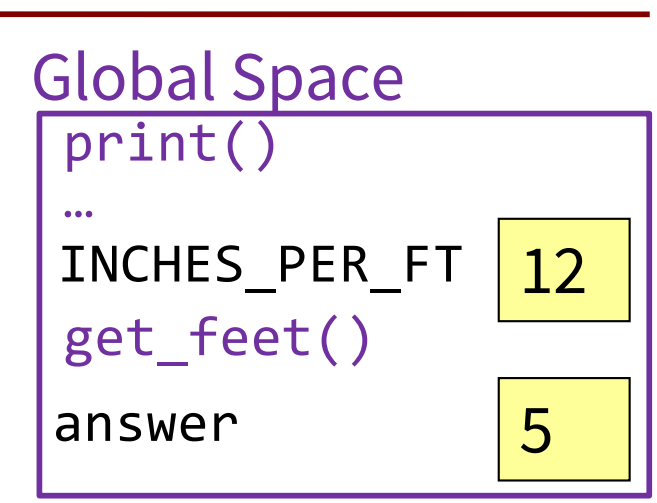


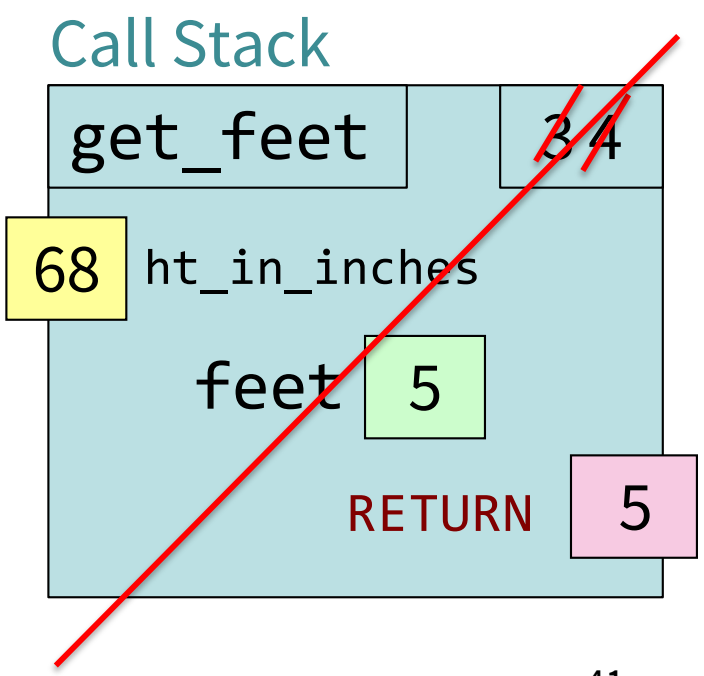
Function Access to Global Space (7)

```
# height3.py

1 INCHES_PER_FT = 12
2 def get_feet(ht_in_inches):
3     feet = ht_in_inches // INCHES_PER_FT
4     return feet

5 answer = get_feet(68)
6 print(answer)
```





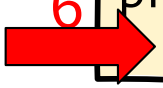
Python has just executed line 5.
A new global variable answer has been created.
The call frame for get_feet has been deleted.

Function Access to Global Space (8)

```
# height3.py

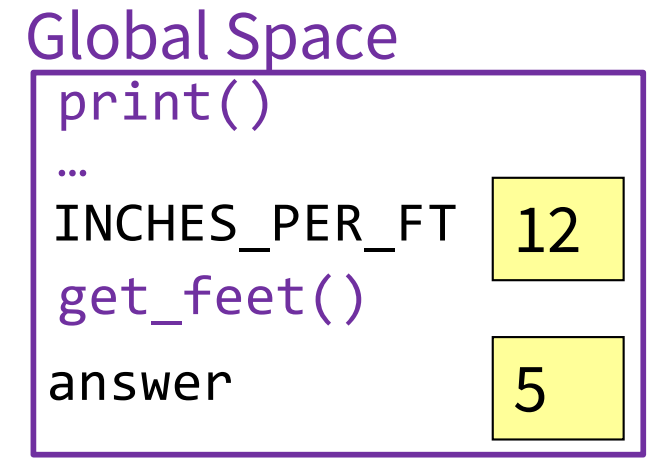
1 INCHES_PER_FT = 12
2 def get_feet(ht_in_inches):
3     feet = ht_in_inches // INCHES_PER_FT
4     return feet

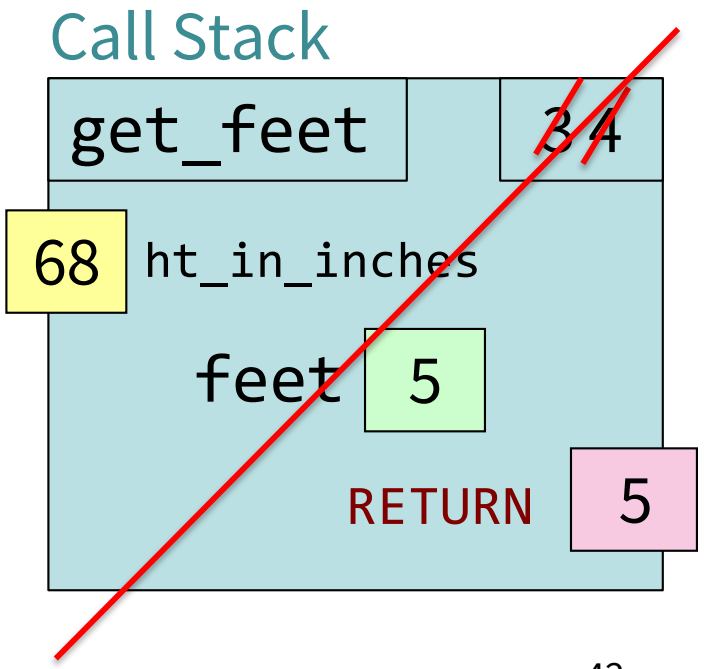
5 answer = get_feet(68)
6 print(answer)
```



Python has just executed line 6.

```
C:\> python height3.py
5
```





Function Access to Global Space (9)

```
# height3.py

1 INCHES_PER_FT = 12
2 def get_feet(ht_in_inches):
3     feet = ht_in_inches // INCHES_PER_FT
4     return feet

5 answer = get_feet(68)
6 print(answer)
```

Python has completed executing all lines of the module. Python is no longer running, so the global space is gone. You can type a new command at the command line now.

```
C:\> python height3.py
5
C:\>
```

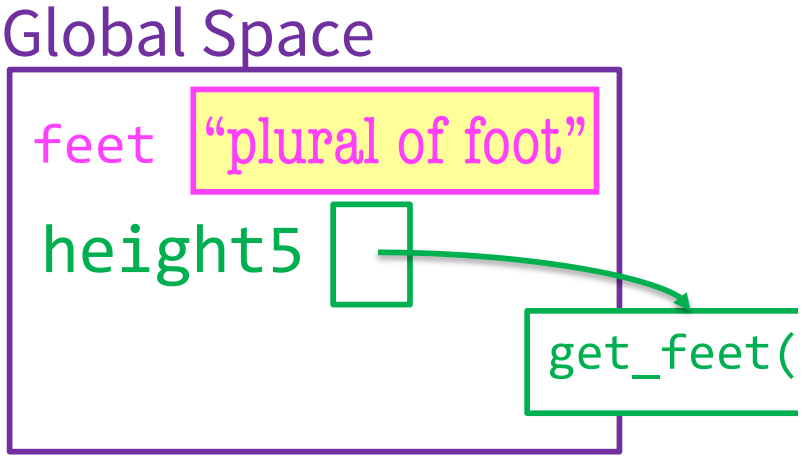
Q: what about this??

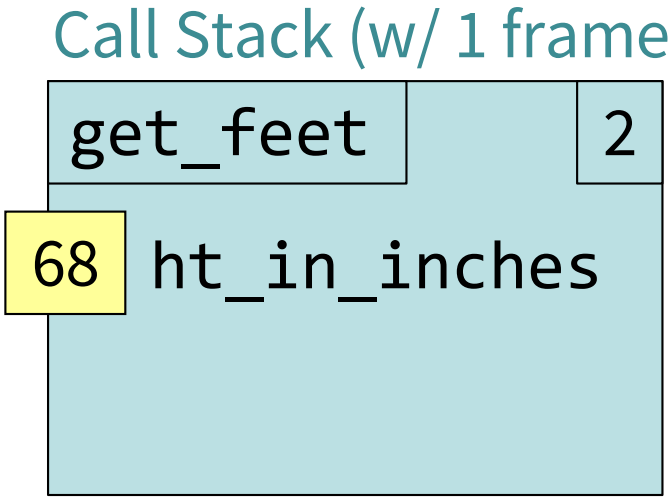
What if a local variable inside a function has the same name as a global variable?

```
# height5.py

1 def get_feet(ht_in_inches):
2     feet = ht_in_inches // 12
3     return feet
```

```
C:\> python
>>> feet = “plural of foot”
>>> import height5
>>> height5.get_feet(68)
```





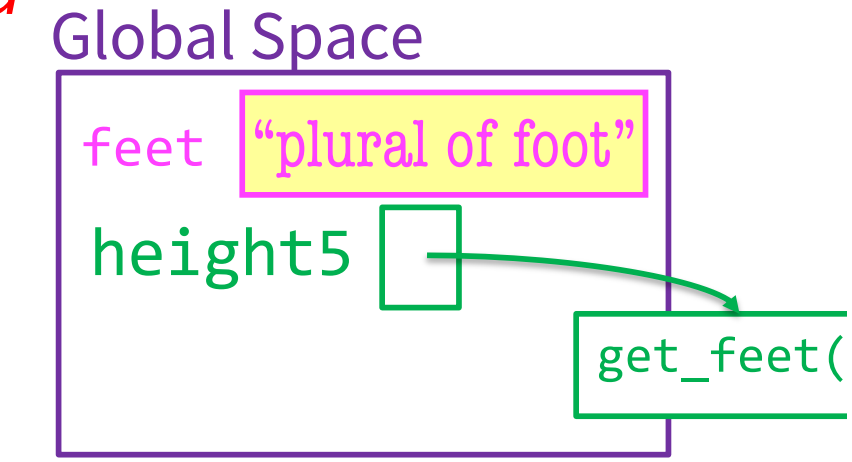
A: **Look, but don't touch!**

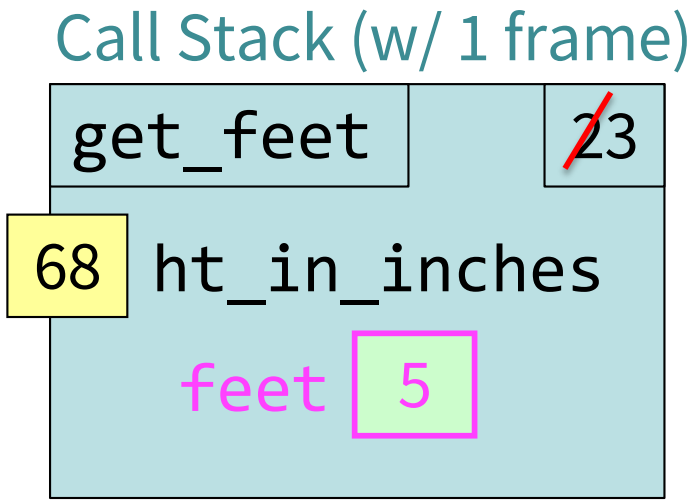
Can't change global variables in a function! Assignment to a global makes a new local variable!

```
# height5.py

1 def get_feet(ht_in_inches):
2     feet = ht_in_inches // 12
3     return feet
```

```
C:\> python
>>> feet = "plural of foot"
>>> import height5
>>> height5.get_feet(68)
```





Use Python Tutor to help visualize

Lots of code for today:

https://www.cs.cornell.edu/courses/cs1110/2022sp/schedule/lecture/lec04/lec04.html

Paste it into the Python Tutor (http://cs1110.cs.cornell.edu/tutor/#mode=edit)

- Visualize the code as is
- Change the code
  - Try something new!
  - Insert an error! (misspell **`ht_in_inches`** or **`feet`**)
- Visualize again and see what is different

Call Frames and Global Variables

```
# bad_swap.py
def swap(a,b):
    """Bad attempt at swapping
   globals a & b"""
    tmp = a
    a = b
    b = tmp

a = 1
b = 2
swap(a,b)
```

Question: Does this work?

What exactly gets swapped with function **swap**?

Paste this into the Python Tutor and see for yourself!

More Exercises (1)

Module Text

```
# my_module.py

def foo(x):
    return x+1

x = 1+2
x = 3*x
```

Python Interactive Mode

```
>>> import my_module
>>> my_module.x
…
```

What does Python give me?

A: 9
B: 10
C: 1
D: Nothing
E: Error

More Exercises (2)

Function Definition

```
# silly.py

def foo(a,b):
    x = a
    y = b
    return x*y+y
```

Function Call

```
>>> import silly
>>> x = 2
>>> foo(3,4)
>>> x
…
```

What does Python give me?

A: 2
B: 3
C: 16
D: Nothing
E: I do not know

More Exercises (3)

Module Text

```
# module.py

def foo(x):
    x = 1+2
    x = 3*x
```

Python Interactive Mode

```
>>> import module
>>> module.x
…
```

What does Python give me?

A: 9
B: 10
C: 1
D: Nothing
E: Error

More Exercises (4)

Module Text

```
# module.py

def foo(x):
    x = 1+2
    x = 3*x

x = foo(0)
```

Python Interactive Mode

```
>>> import module
>>> module.x
…
```

What does Python give me?

A: 9
B: 10
C: 1
D: Nothing
E: Error

More Exercises (5)

Module Text

```
# module.py

def foo(x):
    x = 1+2
    x = 3*x
    return x+1

x = foo(0)
```

Python Interactive Mode

```
>>> import module
>>> module.x
…
```

What does Python give me?

A: 9
B: 10
C: 1
D: Nothing
E: Error
